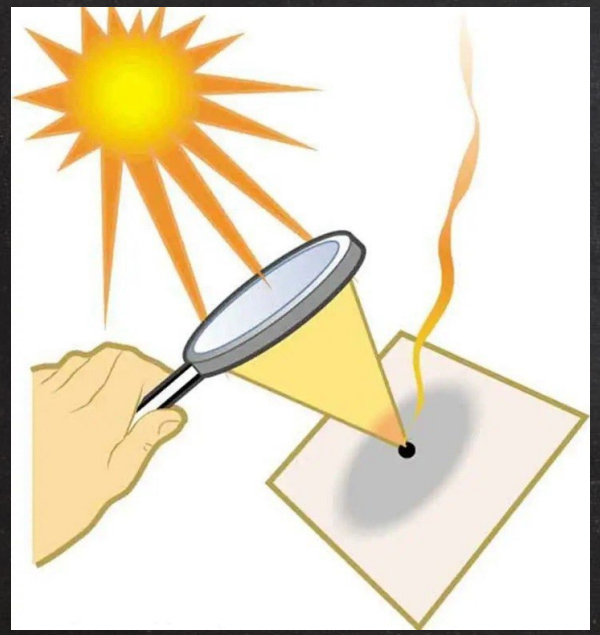
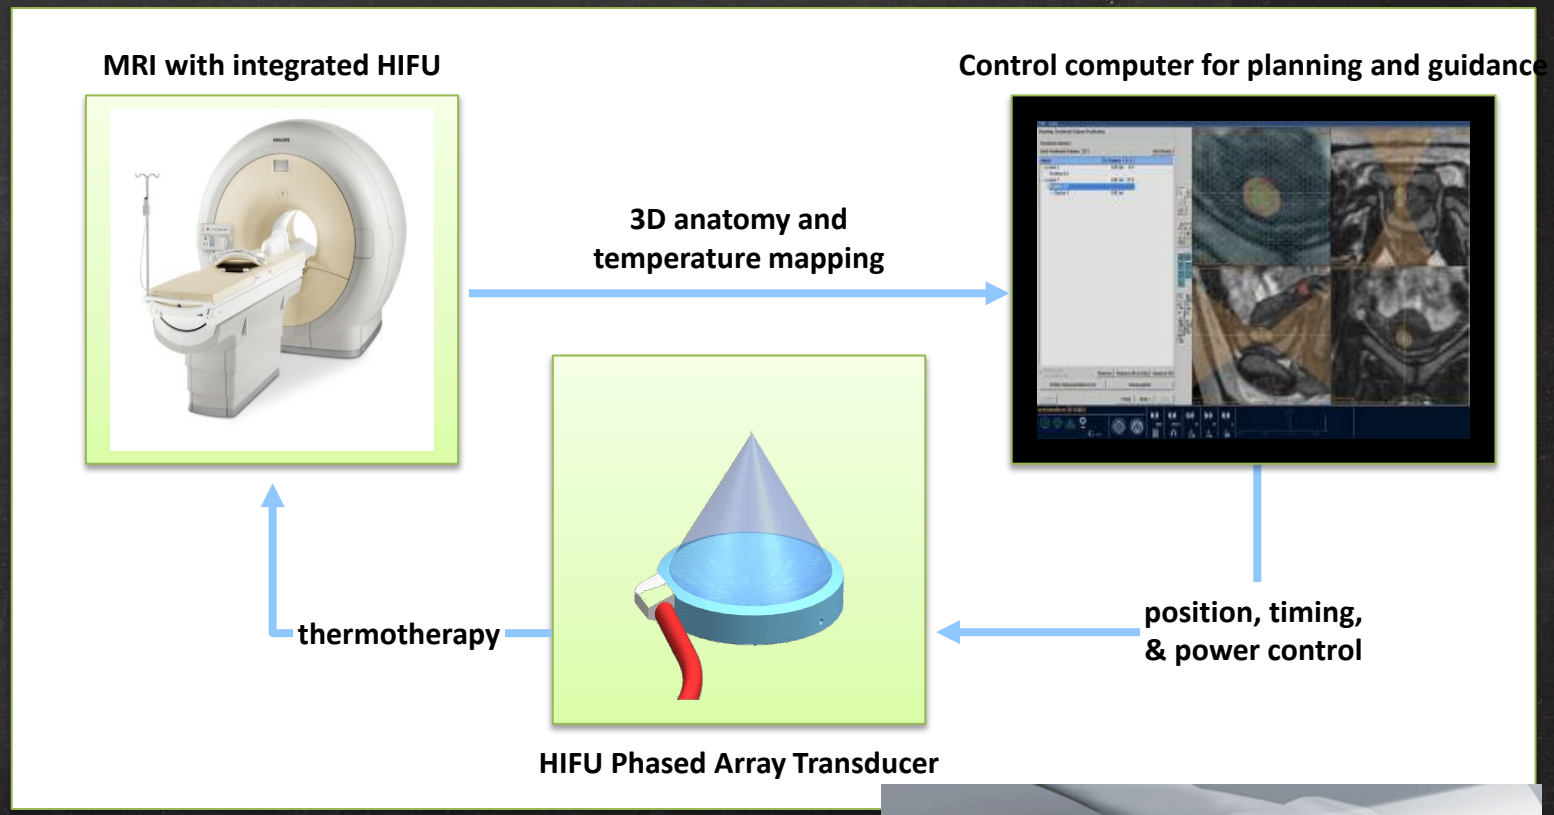
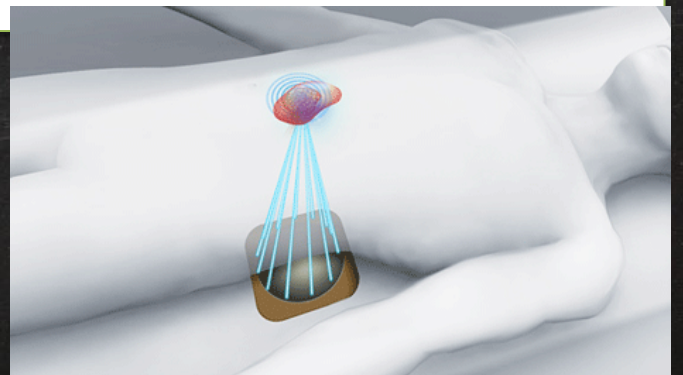
# FUS/HIFU

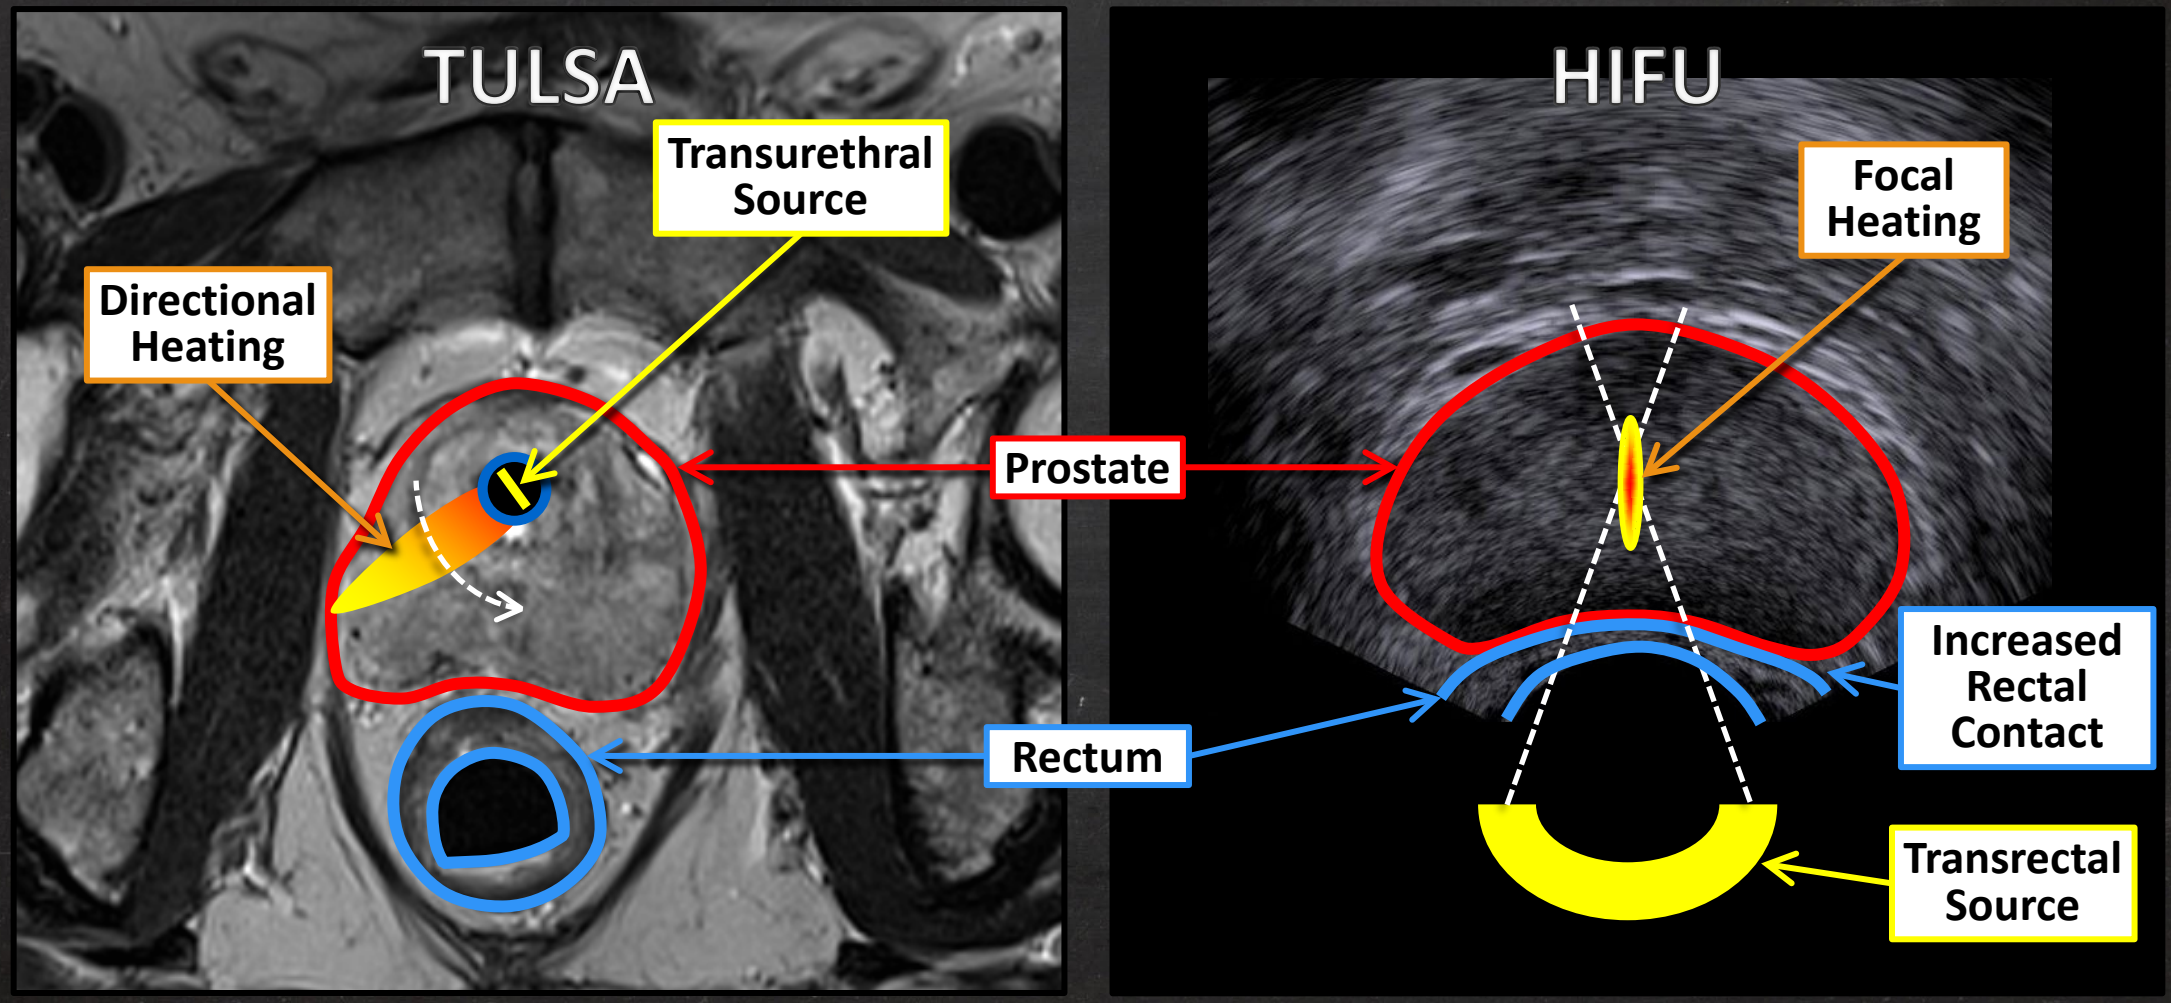
- HIFU: High-Intensity Focused ultrasound







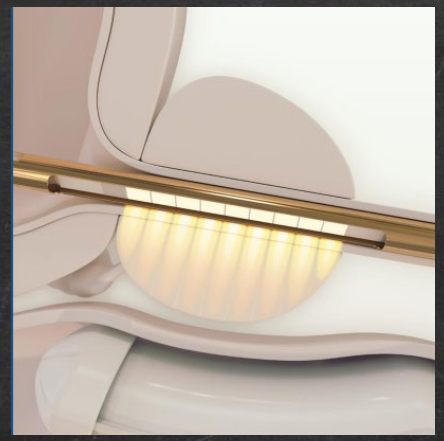
# FUS versus HIFU: Anatomy



* Images and overlays for illustrative purposes only

# FUS/HIFU

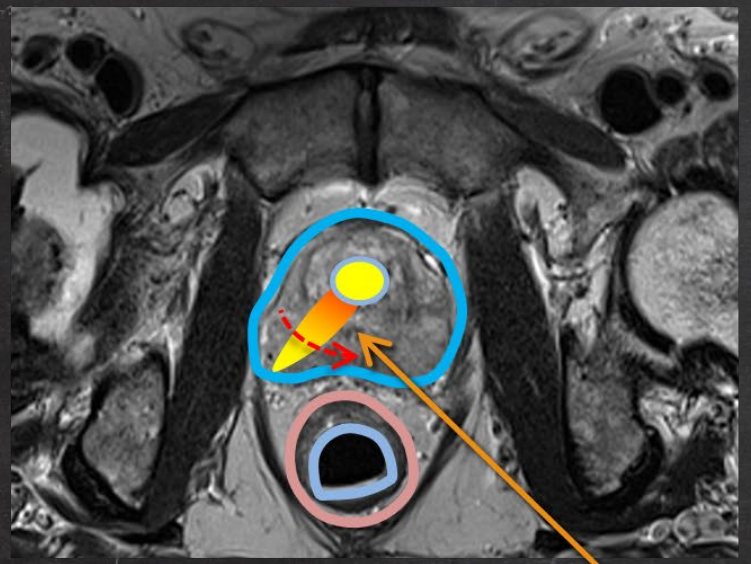
- FUS: 10  five mm Sonications

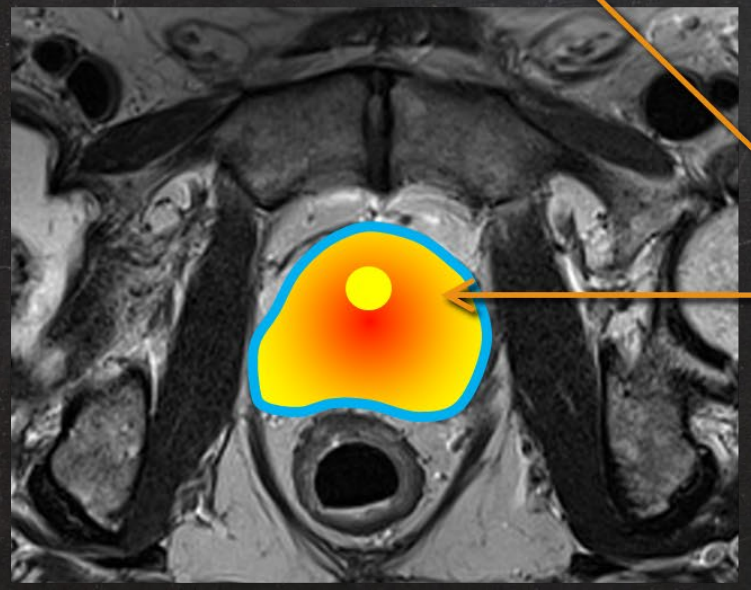


# MRI-Guided Transurethral Ultra-Sound Ablation (TULSA)

- Transurethral directional ultrasound
  - Incision-free, inside-out ablation
  - Sweeping ultrasound, continuous rotation (large, uniform ablation volumes)
  - Active cooling of urethra and rectum
- MRI-guided planning and robotic device positioning
- Real-time MRI thermal dosimetry and closed-loop ablation control
  - Delivers thermal therapy, measures temperature effect in real time, automatically adjusts the energy delivered

# TULSA vs. HIFU





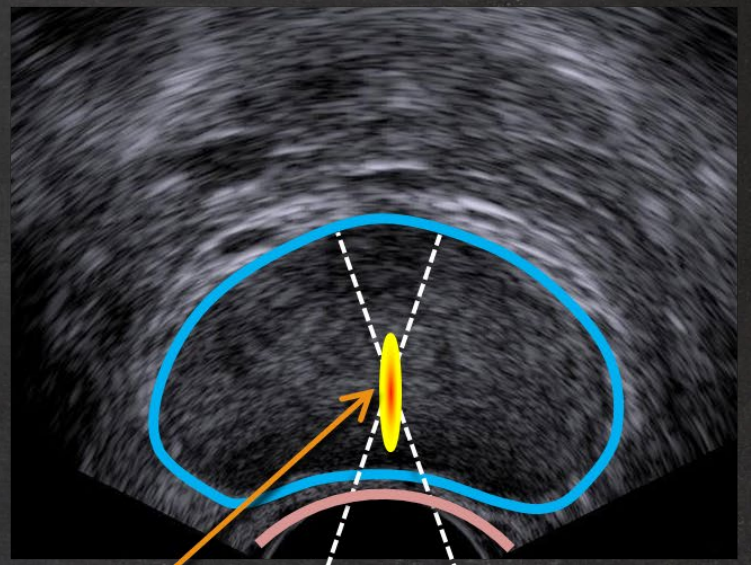
**Prostate**

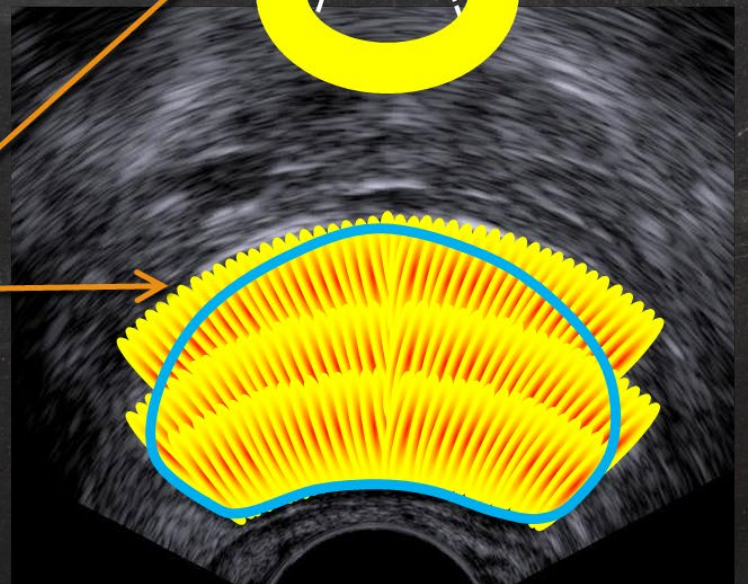
| Source Energy | |
|---|---|
| Trans-urethral | Trans-rectal |

| Cooling | |
|---|---|
| Yes | No |

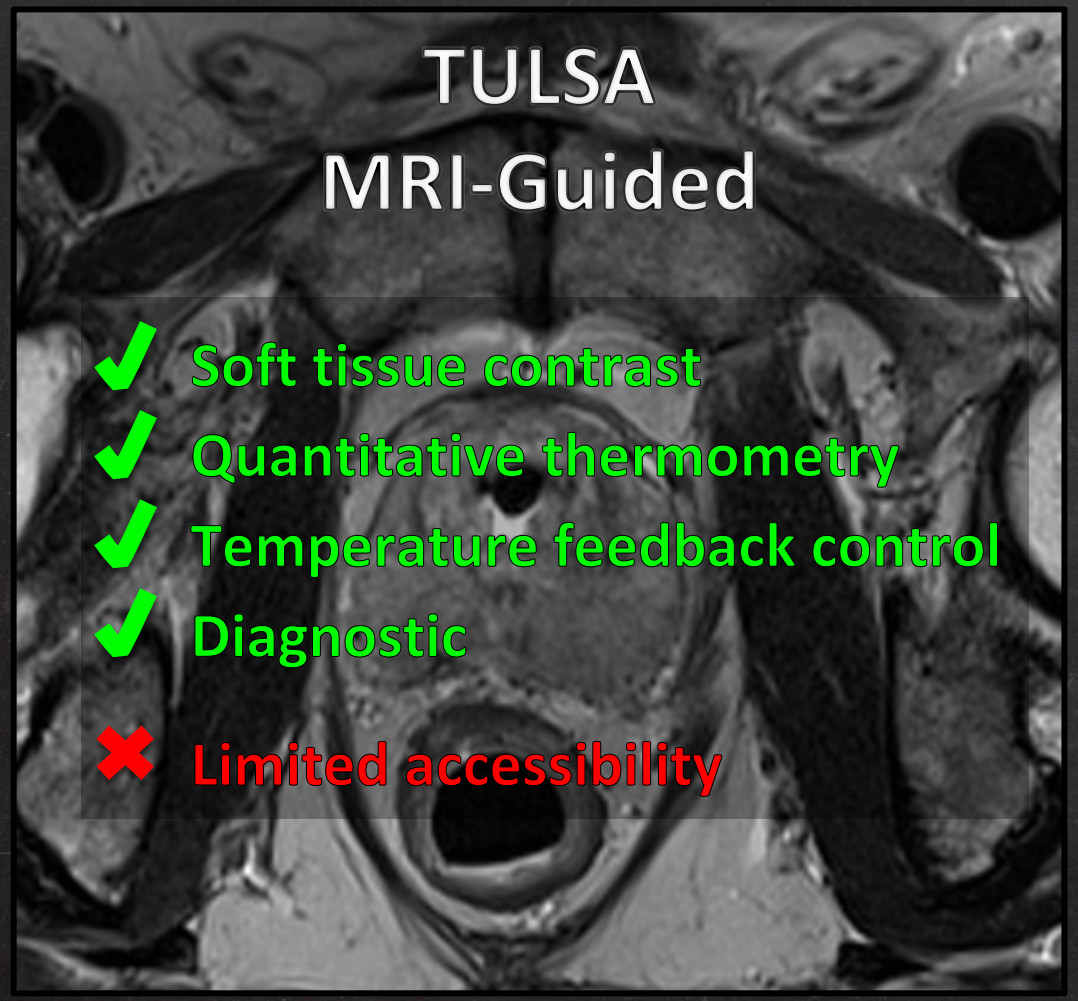
| Heating | |
|---|---|
| Directional | Focal |
| Continuous (Inside -> Out) | Discrete (Outside -> In) |

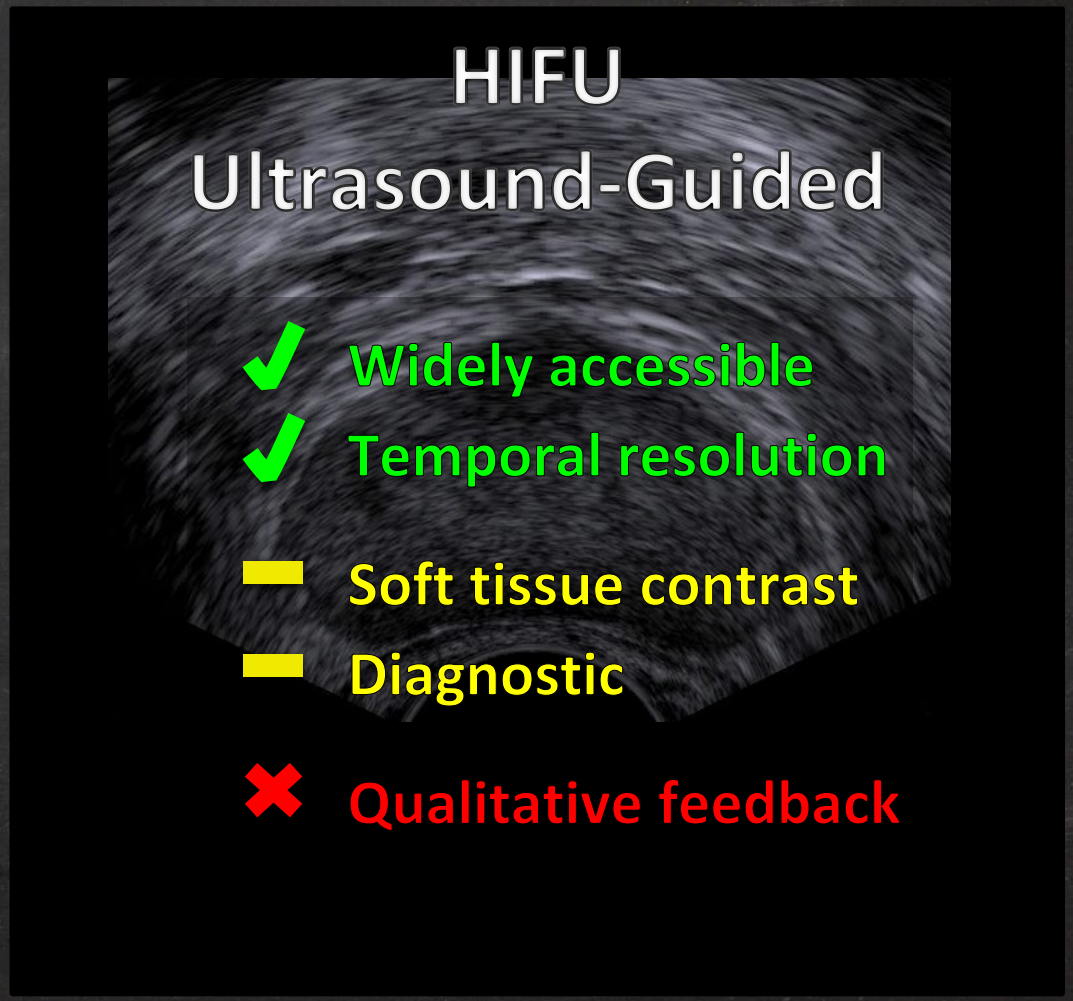
**Rectum**





# FUS versus HIFU: Imaging





# MRI-Guided Transurethral Ultra-Sound Ablation (TULSA) Technology

## Control Room

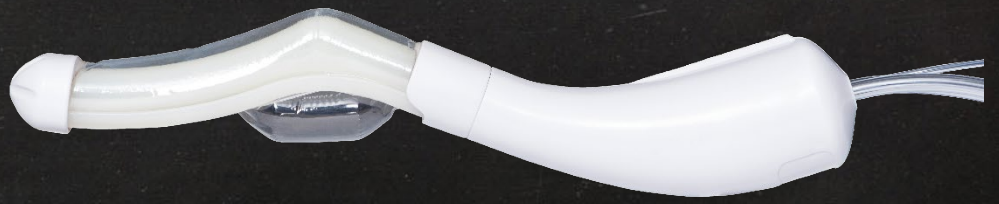
Treatment Delivery Console

- Fluid circuit for UA and ECD
- System electronics to power and control all system components

## MRI Room

**Ultrasound Applicator (UA)**

**Endorectal Cooling Device (ECD)**

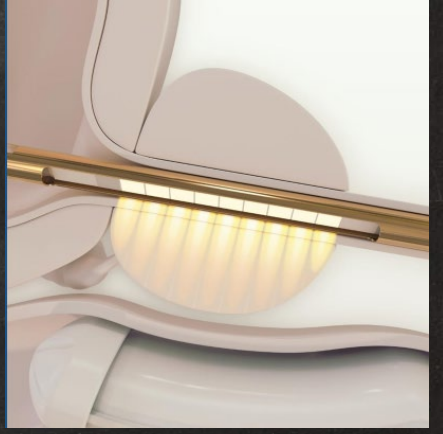


# SYSTEM COMPONENTS

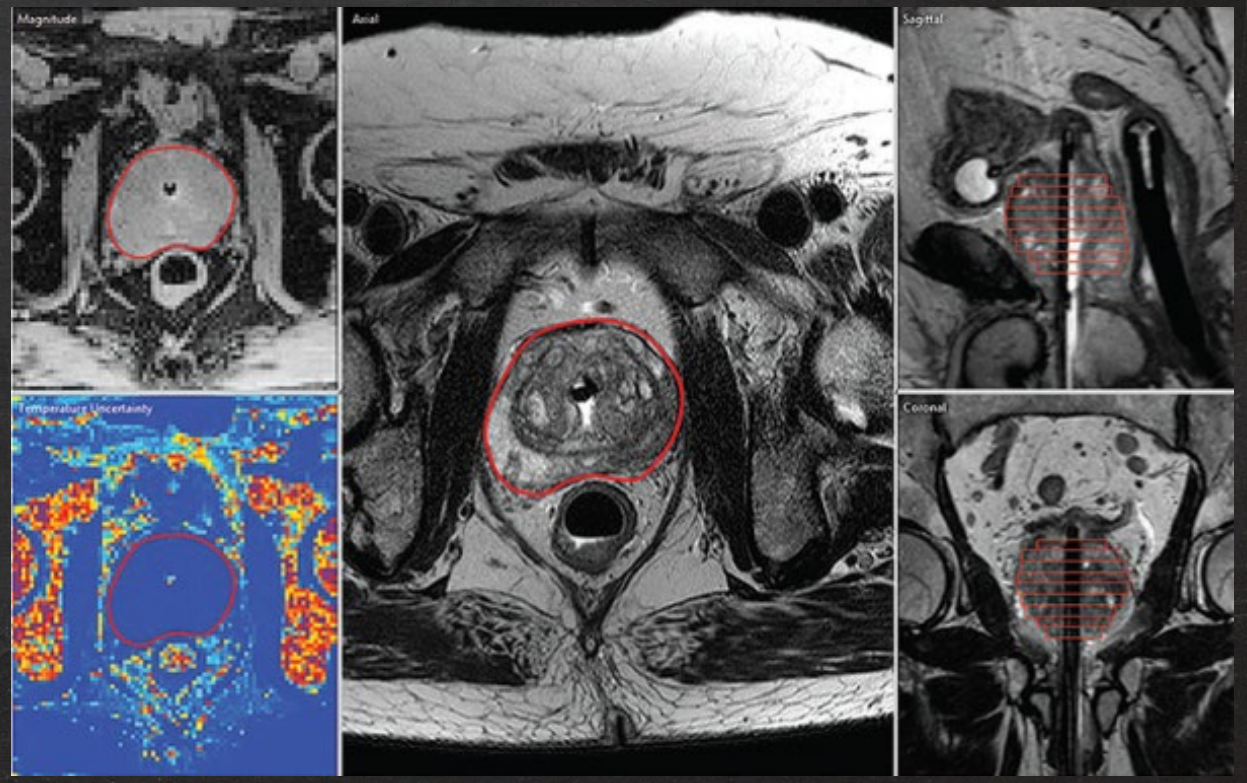
## Ultrasound Applicator (UA)

10 independent ultrasound transducer elements;
4 & 13 MHz; 0 to 4 W acoustic / element
Rigid catheter; Size 22 French; Sterile, single-use

# FUS Technology



- With the patient in the MRI bore, physicians create 3D treatment plans using real-time visualization.
- Ablation using real time MRI imaging and thermometry



# TULSA MR Thermometry

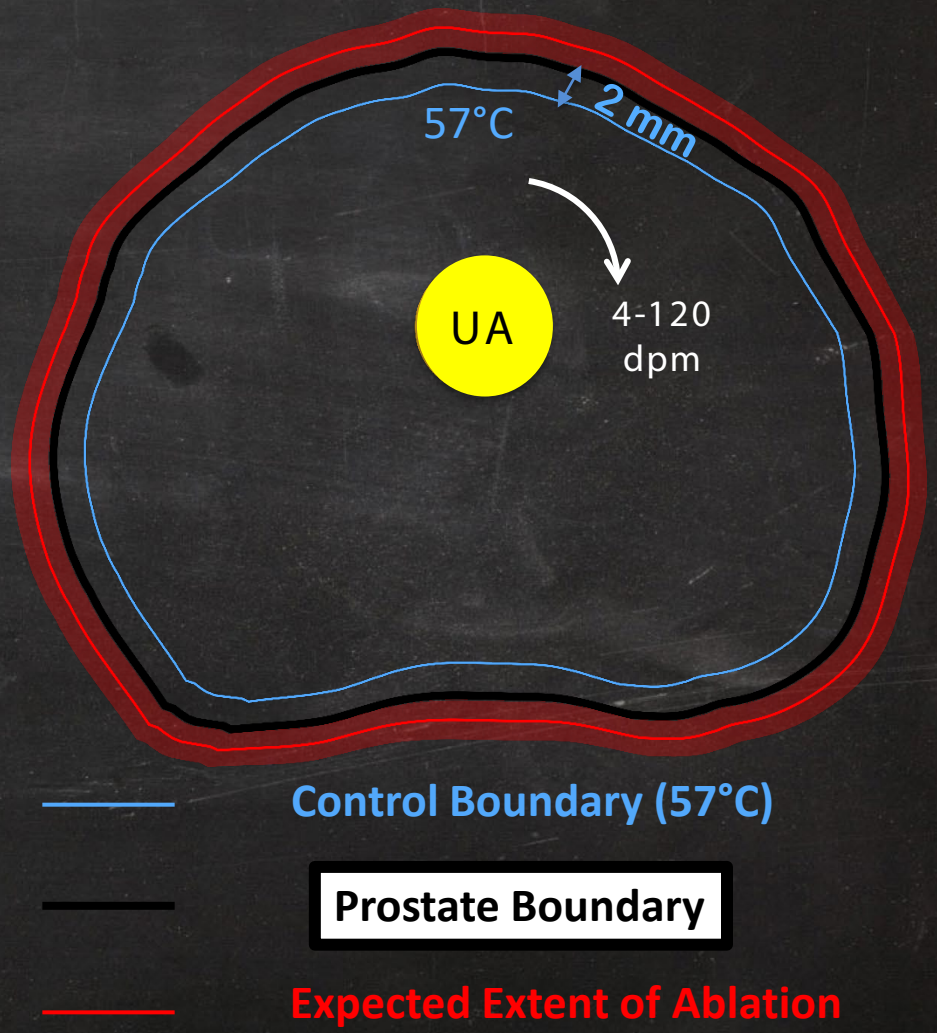
- UA power and rotation speed are controlled according to:
  - The real-time temperature at the control boundary

    (57°C within 2 mm of the prostate boundary)

  - The real-time maximum temperature within the monitoring margin

    (maintained below 86°C to avoid tissue boiling)

  - Possibility of boost to increase size with temperature



# TULSA MR Thermometry

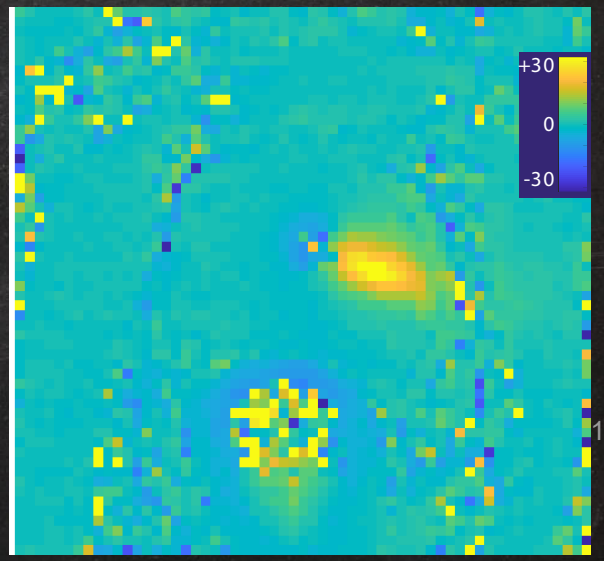
- Based on the Proton Resonance Frequency Shift Method
- Temperature difference is calculated from subtracted phase images

Phase 1
(Before Heating)

Phase 2
(During Heating)

Phase Difference

Temperature Map
(Temperature Difference [°C])



# TULSA MR Thermometry

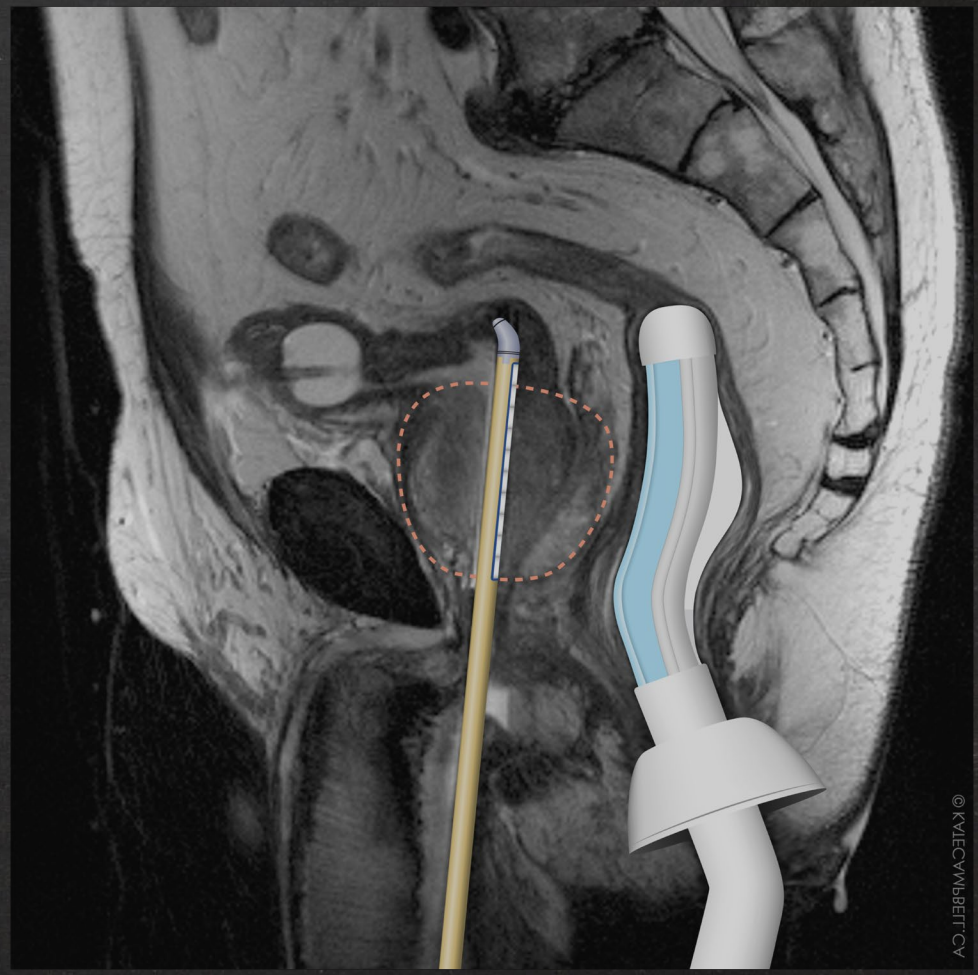
TULSA MR-Thermometry:

- is obtained with a relative measure, thus needing an external baseline temperature (i.e., patient's baseline temperature measured prior to starting the treatment)
- Is only valid in water-based tissues (not for fat tissue!)
- !! Does not distinguish temperature changes from motion (i.e., general anesthesia is required)

# INITIAL IMAGING

## Gross Device Positioning

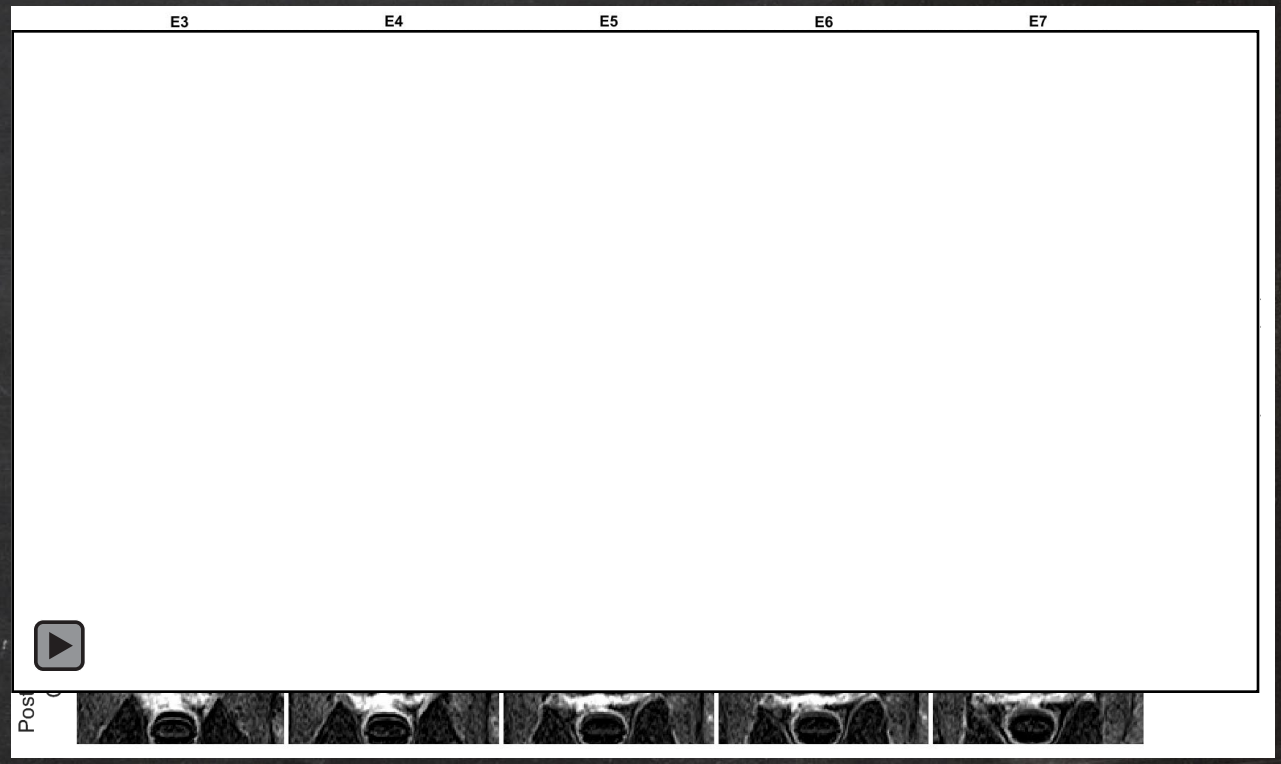
- Acquire gross positioning MR images (localizer / sag 2D) to determine the position of UA and ECD.
- Ensure UA is through the bladder neck.
- If there is air between ECD and anterior rectal wall, or if ECD is not facing prostate, manually adjust ECD and re-acquire images.



# DELIVERY

## Monitor Treatment Delivery

- Assess beam alignment, heating depth, artifacts, and patient motion
- Possibility of to deactivate elements, adjust UA beam angle, or edit boundary



# TULSA Indications

**Established**

- Whole-gland TULSA in patients with localized prostate cancer and:
  - Gleason Grade Group 1-2
  - Stage ≤ T2
  - PSA ≤ 15 ng/ml

**Within research protocols**

- Salvage treatment in biochemically (prostate-specific antigen higher than nadir or > 2 ng/ml) radio-recurrent prostate cancer
- Focal treatment in prostate cancer (T1-T2a; Gleason score ≤ 7; PSA < 15 ng/ml) patients being scheduled for radical prostatectomy
- Palliation of symptomatic locally advanced prostate cancer
- Treatment for large and symptomatic benign prostatic hypertrophy (BPH)

# TULSA Contraindications

**General**

- General contraindications to MRI
- Patients unfit for general anesthesia
- Large prostate calcifications along the US beam path
- Large prostate cysts along the control boundary
- Infections

**In patients needing radical prostate cancer ablation**

- Extracapsular tumor extension
- Metastases
- Tumour within 3-mm of the urethra or the external sphincter

**In patients needing whole-gland treatment**

- Prostate sagittal length > 5.0 cm (For single segment treatment)
- Prostate axial diameter > 6.0 cm

# TULSA Step-by-step Workflow

## Step 1: Probe Positioning

- Acquire MR images (localizer / sag T2)
- Determine the position of UA and ECD
- Ensure UA is through the bladder neck
- If there is air between ECD and anterior rectal wall, or if ECD is not facing prostate, manually adjust ECD and confirm the new position with newly acquired images

# TULSA Step-by-step Workflow

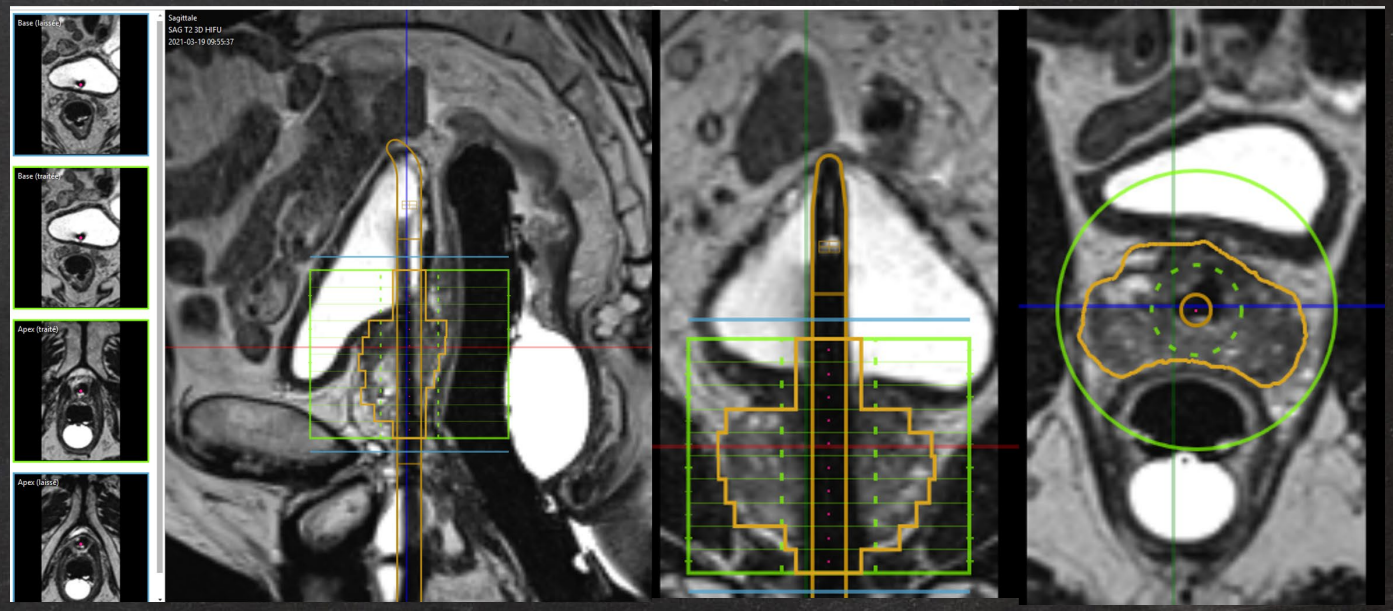
## Step 2: Device Registration

- Acquire & load 3D T2W images on TULSA MRI console
- Verify ECD and UA positioning in 3 planes
- Align graphical representation of the UA to the actual UA displayed on the MRI images

# TULSA Step-by-step Workflow

## Step 3: Define UA Treatment Location (Coarse)

- Move UA overlay to align the treatable volume with target tissue, and avoid critical structures (external urinary sphincter, bladder neck) from the treatment plan
- 4 mm safety overlay indicates tissue that are expected to be fully spared

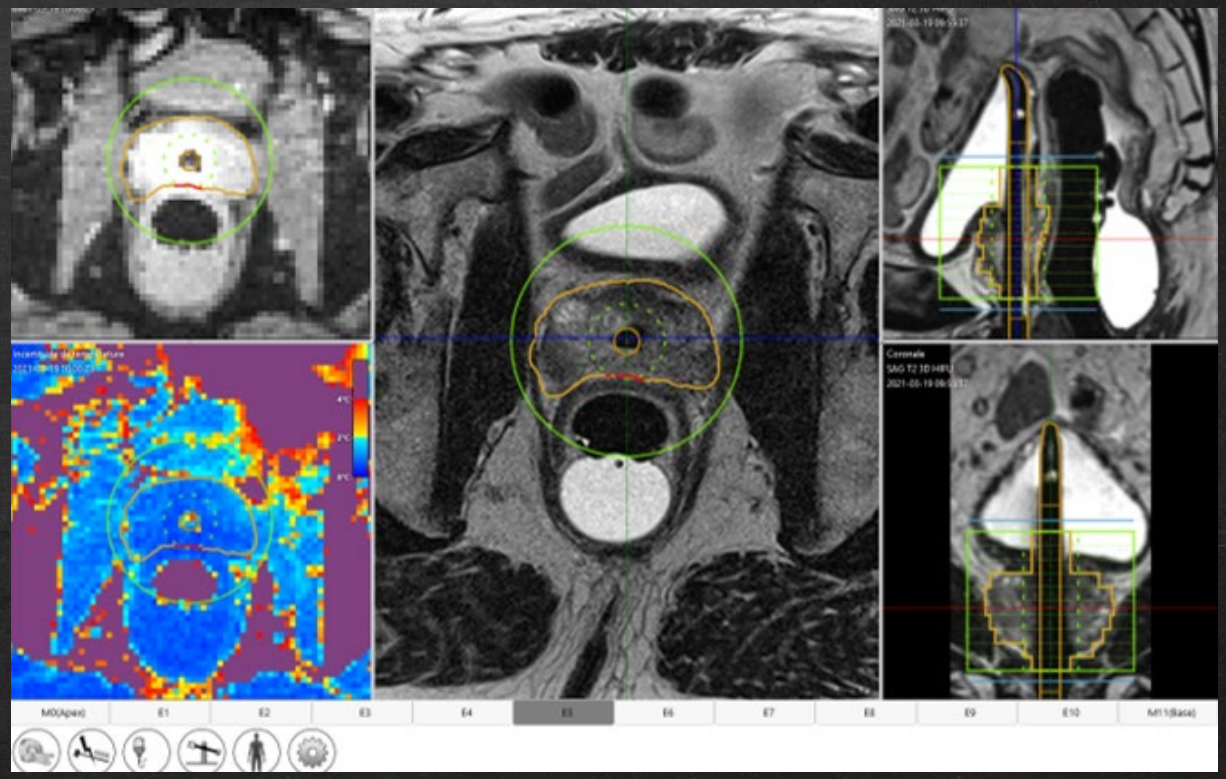


- The robotic positioning system automatically moves the UA along the linear axis to the desired treatment location and confirms the final position with newly acquired T2W MRI images

# TULSA Step-by-step Workflow

## Step 4: Treatment Boundaries and Thermometry Quality

- Acquire thermometry images aligned to UA elements
- Acquire and open Ax T2W images aligned to UA elements
- Adjust for distortion between thermometry and T2W images
- Contour targeted prostate tissue for each active US element



# TULSA Step-by-step Workflow

## Step 5: Energy Delivery

- Define direction of UA rotation and move UA to the desired starting angle
- Input patient's body temperature and start the treatment

# TULSA Step-by-step Workflow

## Step 6: Monitor Treatment

- Pause if patient motion is suspected
- If necessary, deactivate elements, adjust UA beam angle, or edit boundary

- ***Current*** – *color map* of most recent temperature image
- ***Max*** – *color map* of maximum temperature from start of treatment
- ***Motion*** – *difference* between most recent magnitude and first reference
- ***Anatomy*** – most recent magnitude image
- ***Planning*** – most recent AX T2 (not real-time)
- ***Dose*** – colormap of cumulative thermal dose

# TULSA Step-by-step Workflow

## Step 7: Treatment Confirmation and Report

- Acquire post-treatment Ax T1 pre-Gd MR images with UA and ECD in place
- Administer Gd I.V. and acquire post-Gd images to assess the extension of the treated area
- Create a final report of the treatment

# Summary of TULSA Literature

- 6 patients TULSA followed by robotic Prostatectomy 3 weeks after
- Lesion-targeted TULSA demonstrates accurate and safe ablation of PCa. TULSA achieved coagulation necrosis of all targeted tissues. A limitation of this treat-and-resect-study-design was conservative treatment near NVB in patients scheduled for RALP.

ABSTRACT

**Background:** MRI-guided transurethral ultrasound ablation (TULSA) has been evaluated for organ-confined prostate cancer (PCa). The purpose of this study was to assess the safety and toxicity, accuracy and short-term evolution of cell-death after lesion-targeted TULSA.

**Methods:** This prospective, registered, Phase-I treat-and-3-week-resect-study enrolled six patients with MRI-visible-biopsy-concordant PCa. Lesions were targeted using TULSA with radical intent, except near neurovascular bundles (NVB). Robot-assisted-laparoscopic-prostatectomy (RALP) was performed at 3 weeks. Post-TULSA assessments included MRI (1 and 3 weeks), adverse events and quality-of-life (QoL) to 3 weeks, followed by RALP and whole-mount-histology. Treatment accuracy and demarcation of thermal injury were assessed using MRI and histology.

**Results:** Six patients (median age = 70 years, prostate volume = 60 ml, PSA = 8.9 ng/ml) with eight biopsy-confirmed MRI-lesions (PIRADS ≥3) were TULSA-treated without complications (median sonication and MRI-times of 17 and 117 min). Foley-catheter removal was uneventful at 2–3 days. Compared to baseline, no differences in QoL were noted at 3 weeks. During follow-up, MRI-derived non-perfused-volume covered ablated targets and increased 36% by 3 weeks, correlating with necrosis-area on histology. Mean histological demarcation between complete necrosis and outer-limit-of-thermal-injury was 1.7 ± 0.4 mm. Coagulation necrosis extended to capsule except near NVB, where 3 mm safety-margins were applied. RALPs were uncomplicated and histopathology showed no viable cancer within the ablated tumor-containing target.

**Conclusions:** Lesion-targeted TULSA demonstrates accurate and safe ablation of PCa. A significant increase of post-TULSA non-perfused-volume was observed during 3 weeks follow-up concordant with necrosis on histology. TULSA achieved coagulation necrosis of all targeted tissues. A limitation of this

S.M.N. and G.H. contributed equally towards the data analysis and article preparation.

**Objectives**

To report the 3-year follow-up of a Phase I study of magnetic resonance imaging (MRI)-guided transurethral ultrasound ablation (TULSA) in 30 men with localised prostate cancer. Favourable 12-month safety and ablation precision were previously described.

**Patients and Methods**

As a mandated safety criterion, TULSA was delivered as near whole-gland ablation, applying 3-mm margins sparing 10% of peripheral prostate tissue in 30 men. After 12-month biopsy and MRI, biannual follow-up included prostate-specific antigen (PSA), adverse events (AEs), and functional quality-of-life assessment, with repeat systematic biopsy at 3 years.

**Results**

A 3-year follow-up was completed by 22 patients. Between 1 and 3 years, there were no new serious or severe AEs. Urinary and bowel function remained stable. Erectile function recovered by 1 year and was stable at 3 years. The PSA level decreased 95% to a median (interquartile range) nadir of 0.33 (0.1–0.4) ng/mL, stable to 0.8 (0.4–1.6) ng/mL at 3 years. Serial biopsies identified clinically significant disease in 10/29 men (34%) and any cancer in 17/29 (59%). By 3 years, seven men had recurrence (four histological, three biochemical) and had undergone salvage therapy without complications (including six prostatectomies). At 3 years, three of 22 men refused biopsy, and two of the 22 (9%) had clinically significant disease (one new, one persistent). Predictors of salvage therapy requirement included less extensive ablation coverage and higher PSA nadir.

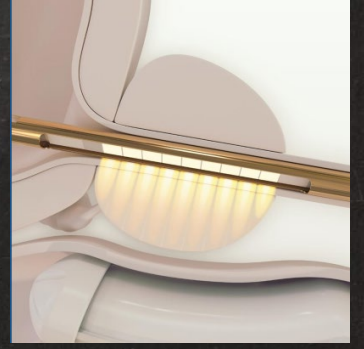
**Conclusion**

With 3-year Phase I follow-up, TULSA demonstrates safe and precise ablation for men with localised prostate cancer.

# Summary of TULSA Literature

- The optimal timing of MRI follow-up seems to be at the earliest at three weeks after treatment, when the post-procedural edema has decreased and the NPV has matured.
- Diffusion-weighted imaging has little or no added diagnostic value in the subacute setting.
- Mäkelä P, Anttinen M, Suomi V, Steiner A, Saunavaara J, Sainio T, Horte A, Taimen P, Boström P, Blanco Sequeiros R. Acute and subacute prostate MRI findings after MRI-guided transurethral ultrasound ablation of prostate cancer. Acta Radiol. 2021

# ADVANTAGES



- Less invasive than cryotherapy, electroporation and laser phototherapy.
- The FUS transurethral route is the best approach to treat the anterior portion of the prostate.
- Perspective of focal cancer treatment
- Relieve of Lower Urinary Tract Symptoms (LUTSs)

- Elterman D, et al. Relief of Lower Urinary Tract Symptoms After MRI-Guided Transurethral Ultrasound Ablation for Localized Prostate Cancer: Subgroup Analyses in Patients with Concurrent Cancer and Benign Prostatic Hyperplasia. J Endourol. 2021

## Salvage open radical prostatectomy for recurrent prostate cancer following MRI-guided transurethral ultrasound ablation (TULSA) of the prostate: feasibility and efficacy

Shiva Madhwan Nair[a], Noah Stern[a], Malcolm Dewar[b], Khurram Siddiqui[c], Elliot Smith[d], Jose A. Gomez[e], Madeleine Moussa[e] and Joseph L. Chin[a]

[a]Division of Urology, Department of Surgery, Western University, London, ON, Canada; [b]Life Kingsbury Hospital, Cape Town, South Africa; [c]Department of Surgery, Sultan Qaboos University Hospital, Muscat, Oman; [d]University of Toronto, Toronto, ON, Canada; [e]Department of Pathology, Western University, London, ON, Canada

**ABSTRACT**

**Introduction:** MRI-guided transurethral ultrasound ablation (TULSA) is a novel modality for minimally invasive ablation in patients with localised prostate cancer (PCa). A multi-national Phase 1 (30 patients) and subsequent Phase 2 (115 patients) study showed TULSA to be feasible, safe and well tolerated. However, technical viability and safety of salvage prostatectomy for those who failed TULSA is unclear. Herein, we report the feasibility and morbidity of salvage radical prostatectomy (sRP) post-TULSA.

**Methods:** Four patients with biopsy-proven residual cancer following TULSA underwent open retropubic sRP within 39 months of TULSA. Peri-and post-operative morbidity were reported. Detailed histopathologic assessment is reported.

**Results:** Median follow-up was 43 months after sRP. Mean operating times, blood loss, and length of stay were 210 min, 866 ml, and 3.5 days, respectively. Intraoperative finding of some fibrotic reaction of endopelvic and Denonvilliers fascia was characteristic. There were no perioperative complications. Whole-mount pathology sections showed one pT2b and three pT3a, suggesting under-staging pre-TULSA. Location of disease was compatible with persistent cancer mostly in the untreated peripheral safety region. One man received an artificial urinary sphincter. All men experienced erectile dysfunction responsive to treatment. Two patients with positive surgical margins had PSA progression requiring salvage radiation, with one requiring long-term androgen deprivation therapy.

**Conclusions:** RP is a viable and safe salvage option if TULSA fails. Technical difficulty and perioperative morbidity were negligible and attributable to minimal peri-prostatic reaction from TULSA.

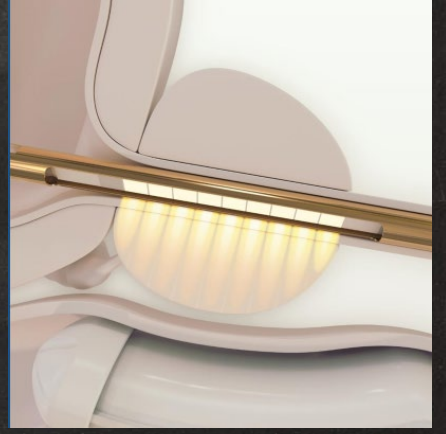
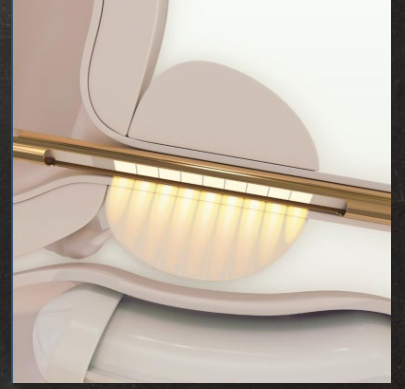
Salvage prostatectomy; MRI guided; TULSA; localised prostate cancer

# Conclusions



- ✓ TULSA provides minimally invasive thermally-mediated destruction of prostate tissue through directed, non-focused, ultrasound energy
- ✓ Real-time MR-thermometry is continuously acquired during treatment to provide temperature maps useful in adjusting the frequency and power for each transducer element
- ✓ TULSA treatments follow a step-by-step workflow

# Conclusions



- ✓ TULSA is currently indicated for prostate tissue ablation. The pivotal study included patients with localized prostate cancer:
  - ✓ Gleason Grade Group 1-2
  - ✓ Stage ≤T2
  - ✓ PSA ≤15 ng/ml

- ✓ Promising results have been published on TULSA for recurrent and higher-grade cancer and concurrent BPH and cancer

- ✓ Further prospective multicenter trials are warranted to confirm the clinical scenarios that may benefit the most from this emerging technology
